Instructor: Dr. Min Zhou

Course Description:
The purpose of this course is to introduce useful statistical methods (especially multivariate regression models) for social scientists, including various extensions of linear models, logistic models, and count models. In each class, we will both study the statistical model and its empirical application in substantive fields. For sociology students, the most helpful way to study a statistical model is probably to look at how it can be employed to address sociological questions in practice. The course provides an overview of useful techniques, rather than going into great technical details. We will discuss some pertinent statistical theory in class sessions, but the emphasis will be on applications.

We will do data analysis with the aid of a software package Stata. The computing facilities on campus have Stata on their computers. As an important part of this course, the lab will teach you how to use Stata. Attendance at labs is mandatory. More information will be provided by our lab instructor Ruth Kampen.

Course Outcomes/Objectives:
At the end of this course, hopefully you will have sufficient familiarity with regression techniques to (1) understand the literature using advanced regression techniques, and (2) apply these procedures properly in your own research. This course will also help lay the foundations for more advanced studies in statistical models. It would be even better if you use the methods learned in this course in your own thesis/research.
